Phase diff c_k & $c_{k_{in}}$ c_{k_0} is @ higher freq. than

If $f_0 = \text{freq}(D_{in})$, rising edge of ck will settle to the middle of the data period

$$\langle V_c \rangle = \frac{\phi}{2\pi} \cdot I_{cp} R \cdot \omega$$

$$f_0 + k_{vco} \langle V_c \rangle = f_{in} \quad \langle V_c \rangle = \frac{f_{in} - f_0}{k_{vco}}$$

If $f_o \neq f_{res} (D_{in})$

* In steady state, $f_{out, v_{ce}} = f_{res} (D_{in})$

$\Rightarrow V_c \neq 0$

\Rightarrow Non-zero phase difference between

CK & D_{in}

$$f_0 + k_{v_{c0}} \cdot V_{c0} = f_{in}$$

$f_n > f_0$ → partially settle with $\langle V_{out} \rangle > 0$
 finally for $k_{v0} \cdot V_c = f_{in}$ $\langle V_c \rangle = 0$
