# ANALOG CIRCUITS : PROBLEM SET 9 

shanthi@ee.iitm.ac.in

## Problem 1

(CURRENT SOURCE) The following configuration acts like a constant current source for varying loads $R_{L}$. Within what range can $R_{L}$ vary ?

Suppose that $R_{L}$ varies from 1 K to $5 \mathrm{~K} . v_{C E}$ must be greater than or equal to 1 volt, always. Also $I_{o}=2 \mathrm{~mA}$; $I_{o} R_{e}=5 \mathrm{~V}, V_{B E}=0.65 \mathrm{~V}$. Find $R_{1}, R_{2}, R_{e}$ and $V_{e e}$ assuming current in the resistors on the base side to be 1 mA .

Figure 1: Problem 1

## Problem 2

$v_{o}$ should just begin to distort at both the ends. Calculate $V_{c c}$ and $V_{e e}$. Take $V_{B E}=0.65 \mathrm{~V}$ nominally. $v_{s}=6 \sin \omega t \mathrm{~V}$.

Figure 2: Problem 2

## Problem 3

(RESISTANCE OF CURRENT SOURCES). Consider the following current sources used in integrated circuits. All unmarked transistors have size (W/L). The device marked 0.25 in part (c) has a size of $0.25(\mathrm{~W} / \mathrm{L})$. All unmarked transistors have a $V_{S G}-\left|V_{T P}\right|=\Delta V$, and an output resistance of $r_{o}$. For each of the current sources, determine the incremental output impedance and the highest voltage that can be supported before one of the devices in the current source goes out of the active region.

Figure 3: Problem 3

## Problem 4

All transistors are identical and the quiescent currents in all three are the same. $V_{E B}$ or $V_{B E}=0.65 \mathrm{~V}$, nominally. For $T_{3}$, $V_{E C Q}=7 \mathrm{~V}$ and $I_{C Q}=2 \mathrm{~mA}$.
Find $R_{1}, R_{2}, R_{3}$ and $V_{C C}$.

Figure 4: Problem 4

## Problem 5

Take $V_{B E}$ or $V_{E B}=0.65 \mathrm{~V}$, nominally. Assume ideal DC functioning with 0 DC offset at the output. Take $V_{T}=25 \mathrm{mV}, \beta=$ 200. Find all dc Q-level voltages and currents.Calculate $k$, $R_{i a}, R_{o a}$.

## Problem 6

$V_{B E}$ or $V_{E B}=0.65 \mathrm{~V}$, nominally. Take $\mathrm{R}=100 \Omega, V_{T}=25 \mathrm{mV}$, $h_{f e}=299$. Current sources $C_{1}$ and $C_{4}$ are ideal while $C_{2}$ and $C_{3}$ have an incremental resistance of $R_{C}$ which is 337.5 K .

Calculate $\mathrm{k}, R_{i a}, R_{o a}$ for small signals.

## Problem 7

Figure 5: Problem 5

Figure 6: Problem 6

Figure 7: Problem 7
Current source $C_{3}$ is ideal while $C_{1}$ and $C_{2}$ have an incremental resistance of $200 \mathrm{~K} . V_{T}=25 \mathrm{mV}, \beta=265$. Find $R_{C}$, $R_{i a}, R_{o a}, \mathrm{k}$ and the CMRR. Find also the allowed swings of $v_{0}$.

## Problem 8

$v_{1}$ and $v_{2}$ are very small signals. $v_{o}=\mathrm{k}\left(v_{1}-v_{2}\right)$. Determine k in sign and magnitude. $V_{T}=25 \mathrm{mV}, \beta=99$. As usual, neglect base currents for operating point calculations.

## Problem 9

Take $V_{B E}=0.65 \mathrm{~V}$, nominally. For the input signal shown both transistors should be swung to their limits of their active regions during the signal cycle. Find $V_{C C}, R_{e}$ and the ratio $R_{x} / R_{y}$. Assume $R_{x} \| R_{y}$ in the order of $R_{e}$.

## Problem 10

Take $V_{B E}=0.65 \mathrm{~V}$, nominally. $V_{\text {smax }}$ is such that both transistors are swung to limits of their active regions during the signal cycle. Find $R_{1}, R_{2}, \mathrm{R}, V_{\text {smax }}$ and $V_{\text {omax }}$.
